### ABSTRACT

A series of Cu (II) complexes of sulphonyl urea derivatives were synthesized and the structures of the newly synthesized compounds were confirmed by FT-IR and <sup>1</sup>H NMR spectral studies. All new derivatives **5(a-d)** were screened for their *in vivo* hypoglycemic activities, it has been found that Cu (II) complexes of sulphonyl urea showed remarkable activity than the parent sulphonyl urea derivatives.

### KEY WORDS

Cu (II) complexes, sulphonyl urea derivatives, hypoglycemic activity

### INTRODUCTION

Diabetes mellitus<sup>1</sup> is a clinical syndrome characterized by hyperglycemia due to absolute (type I) or relative (type II)<sup>2</sup> deficiency of insulin. In both type I (IDDM) and type II (NIDDM) diabetes,<sup>3</sup> the actions of insulin are almost impaired by insensitivity of target tissue. It is characterized by both tissue insulin resistance and an insulin secretory defect. Diabetes mellitus is now recognized as a serious global health problem<sup>4</sup> as it has broken the age barrier and appears even in younger people.<sup>5</sup>

Noninsulin dependent diabetes mellitus (NIDDM) is much more common than IDDM, NIDDM is increasing exponentially worldwide and inviting major health problems from its complications.<sup>6, 7</sup> Various classes of drugs are now available for the controlling of type II diabetes mellitus such as sulphonyl urea, biguanides,  $\alpha$ -glucosidase inhibitors, 2,4-thiazolidinediones and traditional herbal drugs.<sup>8,9</sup>

The sulphonyl urea derivatives have been categorized as first and second generation drugs in these second generation drugs are more potent.<sup>10-12</sup> Sulphonyl urea derivatives and its analogues have been reported to possess excellent biological activities.<sup>13,14</sup> Therefore, sulphonyl urea derivatives are proved to be a useful starting material for physiologically or pharmacological product.

Furthermore, it has been reported that the biological activity of metal complexes is more potent and less toxic as compared to the free ligand.<sup>14,15</sup> In light of these findings, it is

supposed that the introduction of Cu (II) metal to sulphonyl urea moiety may produce derivatives with considerable hypoglycemic activity.

## EXPERIMENTAL

The progress of each reaction was monitored by thin layer chromatography (TLC) by n-hexane:ethyl acetate solvent system. Starting compound acetanilide is of Sigma Aldrich make. Melting points were uncorrected taken in an open capillary tube on a Stuart melting point apparatus. The IR spectra of the compounds were recorded on Shimadzu FTIR Spectrometer with KBr pellets. PMR spectrums were recorded on Bruker Avance 400 MHz NMR Spectrometer.

### General procedure for the synthesis of 4-acetamidobenzene-1-sulfonyl chloride (2)

A mixture of acetanilide (0.148mole) and chlorosulphonic acid (0.77 mole) was refluxed for 1 hour. After the completion of a reaction (monitored by TLC), the reaction mixture was poured over crushed ice to afford a white crystallized product (2) was filtered and dried.

### General procedure for the synthesis of 4-acetamidobenzene-1 sulphonamide (3).

4-acetamidobenzene-1-sulfonyl chloride (2) was mixed with 14 ml ammonia solution and 14 ml of water. The content of the flask was heated at 80°C for 15 minutes. The 4-acetamidobenzene-1-sulfonyl chloride (2) converted into a pasty suspension of corresponding sulphonamide (3). The suspension was cooled in ice and then dil. H<sub>2</sub>SO<sub>4</sub> is added until the mixture was just acidic to congo-red, then formed product(3) was filtered and dried.

### General procedure for the synthesis of sulphonyl urea derivatives 5(a-d)

A mixture of 4-acetamidobenzene-1 sulphonamide (3)(0.005 mole), various substituted phenyl isothiocyanate (4) (0.005 mole) and potassium carbonate (0.50 mole) in acetone 10 mL was refluxed for 5 h. The progress of the reaction was checked using TLC technique. After completion of reaction, the solvent was removed under vacuum and solid mass was poured in ice-cool water. It was then neutralized with acetic acid obtained solid filtered, washed it with ice cold water, dried and recrystallized by ethyl alcohol to afford the target compounds 5(a-d).

### General procedure for the synthesis of preparation of metal Complexes 5(a-d)\*

Metal Complexes were synthesized by employing various methods<sup>16</sup>. In the present work, the metal complexes of Cu (II) with different sulphonyl urea derivatives were synthesized<sup>15</sup> by refluxing the ethanol solution of metal chloride in 1:2 molar ratios. The reaction mixture was refluxed for 3-4 hours. On cooling, the precipitate formed was separated by filtration and washed with cold ethanol followed by petroleum ether and dried over anhydrous CaCl<sub>2</sub> in vacuum.

**Table 1:** Preliminary data of the sulphonyl urea derivatives 5(a-d)

### Hypoglycemic Activity

Assessment of the antidiabetic activity was done according to Alloxin induced diabetes method<sup>17</sup>. Metformin hydrochloride was taken as reference drug. Body weight of each animal in all 10 groups was measured one week before the study. After one week animals were again weighted for fixing the dose of alloxin. Dose of alloxin is given by intraperitoneal route. Blood glucose levels of all animals were measured after 48hrs. Then the dose of compounds was given for 15 days by oral route. After 15 days of compound dosage the glucose levels in blood of each rat was measured and the results were noted.

### Selection of animal species

Healthy young albino rats of either sex weighing between 150 to 220gms (8 to 12 weeks old) were used for acute toxicity study to determine LD<sub>50</sub> of various extracts. Totally there were ten groups, each groups consists of five animals.

### Housing and Feeding Condition

The temperature in the experimental room was around 25°C. Lightening was artificial, the sequence being 12 hours dark, 12 hours light. The conventional laboratory diet was feeded, with an unlimited supply of drinking water.

### Preparation of doses

All the doses were prepared by dissolving 1mg of respective ligand and its complexes in 1ml DMSO and in 1ml Saline solution.

### Administration of doses

The test substances were administered in a single dose by using feeding tube. After fasting for 3-4 hours, rats were weighted and the test substance administered.

### Number of animals and dose levels

In each steps five animals were used. Since there was no information on the substance to be tested (i.e. compounds), starting dose was selected to be 25mg/kg body weight. As it showed no death, the next dose was selected as 50 mg/kg body weight. Finally 47.57kg body weight was considered as the toxic dose and one seventh of this dose was taken as experimental dose for antidiabetic studies.

## RESULTS AND DISCUSSION

Sulphonyl urea derivatives were synthesized from acetanilide (**1**), which on treatment with chlorosulphonic acid gave 4-acetamidobenzene-1-sulfonyl chloride (**2**), in which addition of ammonia gave 4-acetamidobenzene-1sulphonamide(**3**). The 4-acetamidobenzene-1sulphonamide(**3**) treated with various substituted phenyl isothiocyanate **4(a-d)** gives target compounds in good yields. The chemistry of target compounds is quoted in **Scheme 1**.

**Scheme 1:** Synthesis of sulphonyl urea derivatives **5 (a-d)**

The spectra of the metal complexes **5(a-d)** in the area are broad and diffused. The broadening may be the result of the overlap of the bands due to  $\nu(\text{OH})$  of coordinated water molecules which appears as a broad band between  $3200\text{--}3600\text{ cm}^{-1}$ .<sup>18, 19</sup> The synthesized ligands contain C-N linkage, whose frequencies are expected to be in the range of  $1200\text{--}1400\text{ cm}^{-1}$ .<sup>18</sup> A peak in the region  $1244\text{--}1319\text{ cm}^{-1}$  for all the four ligands, has been observed and is assigned to the  $\nu(\text{C-N})$ . In all the metal complexes under study, this band is shifted to higher frequency region and found to appear in the range of  $1531\text{--}1637\text{ cm}^{-1}$ . Such an up shift clearly indicated the involvement of nitrogen in co-ordination with metal atom.<sup>20</sup> M-S stretching vibrations have been observed in the lower region of M-N vibrations i.e. in the range of  $200\text{--}600\text{ cm}^{-1}$ .

In the present study M-S vibrations were in the range of  $205\text{--}532\text{ cm}^{-1}$ . The infrared spectra of the ligand and their metal complexes provide vital information about the bonding. The spectra of complexes exhibit strong absorption bands in the range  $1500\text{--}1600\text{ cm}^{-1}$ . This absorption is associated with the stretching vibration of C=N. The -OH absorption band in the ligands are observed in the region  $3200\text{--}3600\text{ cm}^{-1}$ . This sharp band has disappeared in capacity indicating its involvement in the bond formation process. IR spectrum of ligand **5a** shows characteristic absorption due to -C=S at  $1163$  and at  $1244\text{--}1319\text{ cm}^{-1}$  due to C-N stretching vibrations. The IR spectrum of complex **5a\*** synthesized from ligand **5a** confirms the formation of complex. It clearly indicates the presence of -C=N and C-S bond because -C=N absorption was observed at  $1595\text{ cm}^{-1}$  and absorption at  $684\text{ cm}^{-1}$  due to the presence of C-S. IR spectrum of ligand **5b** shows characteristic absorption due to C=S at  $1423\text{--}1479\text{ cm}^{-1}$  and C-N stretching at  $1269\text{ cm}^{-1}$ . The IR spectrum of complex **5b\*** synthesized from ligand **5b** confirms the formation of complex and indicates the presence of C=N and C-S bond because C=N absorption was observed at  $1606\text{--}1637\text{ cm}^{-1}$  and C-S absorption at  $738\text{ cm}^{-1}$ . IR spectrum of ligand **5c** shows absorption at  $1269\text{ cm}^{-1}$  due to C=S and at  $1319\text{ cm}^{-1}$  due to C-N

bond. The IR spectrum of complex **5c\*** synthesized from ligand **5c** confirms the formation of complex. It indicates the presence of  $\text{-C=N}$  and  $\text{C-S}$  bond because  $\text{C=N}$  absorption takes place at  $1531\text{-}1600\text{ cm}^{-1}$  and  $\text{C-S}$  absorption at  $740\text{ cm}^{-1}$  respectively.

The  $^1\text{H}$  NMR spectra of the some representative metal complexes were recorded. However due to the presence of a metal ion, proton resonance was not expected to take place, and only broad peak were observed in the spectra. Hence the formation of complex was confirmed by comparison data obtained from ligand and the complex.

#### Hypoglycemic Activity Evaluation Study

The synthesized compounds were screened *in vivo* studies for their hypoglycemic activity. The assessment of the activity was done according to Alloxin induced diabetes method. Metformin hydrochloride was taken as reference drug.

It was found that some of sulphonyl urea derivatives and their complexes have shown promising antidiabetic activity compared to the standard metformin hydrochloride. Out of which ligand **5b**, complex **5C\*** and complex **5d\*** have shown significant activity. It has been found that the complexes shown higher antidiabetic activity than the ligands.

**Table 4:** Antidiabetic activity of ligands and their complexes
